

Table 16: Labour-income persistence by income percentile and shock size

Income percentile in $t - 1$	Shock size, by conditional quantile τ						
	5	10	20	50	80	90	95
5	0.91* [0.61,0.96]	0.77* [0.65,0.95]	0.70* [0.65,0.84]	0.51* [0.44,0.57]	0.32* [0.23,0.38]	0.19* [0.10,0.30]	0.12 [-0.09,0.21]
10	0.84* [0.66,0.91]	0.79* [0.71,0.90]	0.77* [0.73,0.84]	0.60* [0.55,0.66]	0.44* [0.37,0.48]	0.34* [0.28,0.42]	0.28* [0.16,0.35]
20	0.76* [0.64,0.84]	0.78* [0.71,0.86]	0.80* [0.75,0.85]	0.68* [0.64,0.73]	0.54* [0.50,0.58]	0.47* [0.43,0.53]	0.43* [0.36,0.50]
50	0.61* [0.52,0.73]	0.70* [0.62,0.76]	0.77* [0.69,0.81]	0.77* [0.74,0.80]	0.68* [0.65,0.71]	0.66* [0.63,0.70]	0.65* [0.59,0.73]
80	0.43* [0.35,0.57]	0.54* [0.46,0.61]	0.64* [0.58,0.71]	0.82* [0.78,0.85]	0.80* [0.76,0.83]	0.82* [0.77,0.86]	0.85* [0.78,0.93]
90	0.31* [0.22,0.45]	0.41* [0.32,0.49]	0.53* [0.46,0.64]	0.83* [0.77,0.88]	0.85* [0.82,0.90]	0.90* [0.84,0.96]	0.97* [0.88,1.06]
95	0.17* [0.02,0.33]	0.23* [0.11,0.37]	0.36* [0.24,0.56]	0.83* [0.73,0.90]	0.90* [0.87,0.96]	0.99* [0.89,1.07]	1.09* [0.94,1.18]

Source: Own elaboration based on the Spanish Survey of Household Finances (EFF, Banco de España) and on the methodological framework of Anghel et al. (2018).

Notes: This table reports own estimates of labour-income persistence across the conditional distribution. Rows refer to the household income position in the previous period, $t - 1$, while columns represent the size of the labour-income shock through the conditional quantile level τ . Each cell reports the estimated sensitivity of current residualized labour income to lagged residualized labour income. The values in square brackets are 90% bootstrap confidence intervals. Confidence intervals are computed by cluster bootstrap at the household level, using 450 replications and resampling the household identifier `pid`. In each bootstrap replication, the full matrix is re-estimated, including standardization, Hermite polynomial basis construction, conditional quantile regressions and evaluation percentiles. The flexible conditional income process is approximated through a tensor-product Hermite polynomial basis, with degree $K_1 = 3$ for lagged income and degree $K_2 = 2$ for age. Quantile regressions are estimated at $\tau \in \{0.05, 0.10, 0.20, 0.50, 0.80, 0.90, 0.95\}$. Asterisks indicate that the 90% bootstrap confidence interval excludes zero. Overall, 48 out of 49 estimated cells are statistically different from zero at the 10% level. Higher values indicate stronger persistence in the corresponding region of the income distribution, whereas lower values indicate greater mobility after the shock.
